17th centuryThe isolation and identification of a novel anti-gastric ulcer drug from fermented tobacco and its mechanism of
action. An extract of fermented tobacco was found to possess an anti-ulcer effect in a pyloric ligation model of rat gastric ulcer.

The activity-guided fractionation of the extract resulted in the isolation of a new benzo[b]thiophene derivative, 2-(p-bromophenyl)-5-ethoxymethylene-3(2H)-benzothiophene-7-ol (V), which was identified by spectroscopic methods. V exhibited significant anti-gastric ulcer activity when given orally (50 mg/kg, p.o.) or intraperitoneally (1.0 mg/kg, i.p.) and it could also significantly increase the activities of gastric acid secretion and antisecretory prostaglandin E2 (PGE2). In addition, it also significantly increased the contents of hydroxyproline, water and mucin in the gastric mucosa and could significantly increase the activities of gastric Na⁺, K⁺-ATPase, Ca²⁺, Mg²⁺-ATPase and adenylate cyclase (AC) but not in the activities of the enzymes involved in glycoprotein synthesis. All these results indicated that the anti-ulcer activity of V may be through promoting the synthesis of mucin and the activities of the enzymes involved in mucin synthesis, and inhibiting the gastric acid secretion. to those who control the climate-control equipment. The majority of electrical devices today contain metal parts that release tiny amounts of mercury and other chemicals. But there is a more serious hidden threat — what's called "household power line radiation." Household power lines, used to supply the light, heat, and power to our homes, run just beneath the surface of the ground, using conductors made of copper. These electrical cables travel through your home from the utility's power plant to your home, and may be connected to your circuit breaker box. In the U.S., electric companies use a voltage of about 110 volts, and household electrical outlets usually have three slots: two horizontal slots to which

The non-volatile memory market, characterized by small size, high density, low power consumption, high speed, and excellent reliability, is one of the most popular categories of semiconductor memory devices. Generally, non-volatile memory devices are widely applied to many fields, such as storage of music, video and images, information technology, telecommunication, personal electronic products, and the like. A conventional non-volatile memory cell generally includes a floating gate. The operation of the floating gate is based on an electrical charge stored within the floating gate, wherein the electrical charge is moved from the source to the drain through a channel region of the floating gate via a channel program and a source erase operation. The basic principle of the floating gate transistor is based on the fact that electrons (negative electrical charge) stored in the floating gate pass through the gate oxide layer to the channel region, thus the threshold voltage of the transistor is increased, and the transistor is turned on. The state of the “turned on” state can be identified by the threshold voltage of the transistor. With the continuous development of technologies, the demand for non-volatile memory devices is also increased. It is particularly significant to produce the characteristics of a non-volatile memory device having high density and high reliability. In conventional radiant heaters of this type, the body of the heater is built into the storck, and a radiant heating plate consisting of a plurality of thin sheets is mounted on the body. In such a conventional radiant heater 2d92ce491b
