Angiotensin I-converting enzyme inhibition in chronic obstructive pulmonary disease: a randomised, double-blind, placebo-controlled trial. Some studies suggest that angiotensin I-converting enzyme (ACE) inhibition can be beneficial in chronic obstructive pulmonary disease (COPD). We tested whether an ACE inhibitor could reduce the decline in forced expiratory volume in 1 s (FEV1) in patients with COPD. This double-blind, randomised, placebo-controlled trial included 256 COPD patients who were selected to have a potentially fast decline in FEV1 (defined as an annual rate of decline of more than 12% in the last 6 months). Patients were treated with fosinopril 20 mg daily or placebo for 6 months, followed by an additional 18 months of follow-up. The primary outcome was a rate of decline in FEV1 over 2 years. The secondary outcome was the change in FEV1 at the end of the 2-year period. Analyses were by intention to treat. 186 patients were assigned to fosinopril and 70 to placebo, and 185 patients were included in the analysis. At the end of 2 years, there were no differences in the rate of decline in FEV1 between the two groups (mean difference 0.05 litres [95% CI -0.14 to 0.24]; $p=0.61$). Patients in both groups showed a significant decline in FEV1 during follow-up. In the patients who received fosinopril there was a significantly greater improvement in the rate of decline (p

In this special issue of *Experimental Dermatology* we aim to provide readers with an overview of a diversity of topics of the skin that have been dealt with over the last few months in the various sections of the journal. We hope that this issue will provide an overview of the most recent developments in the field of skin biology. Ointments have become an important area in dermatology with the commercial development of emollient-containing cosmetics, 2d92ce491b
