Pascal Analyzer is an advanced tool for analyzing, compiling and debugging source code files. With the software, you can make use of many different features that will help detect errors, optimization problems, compilation warnings, and much more. Pascal Analyzer detects potential problems within your source code files, such as identifying syntax errors, unused variables, redundant code, inconsistent text cases, warnings and much more. After the analysis is done, the user interface allows you to generate a number of reports that you can view and export to various formats. These reports can be saved to various file formats, including a directory, an XML file and a CSV file. The file can be easily viewed, exported and printed. You can open your PAS, DPK or DPR file within the Pascal Analyzer application, with the option to sort the list according to the contents. You can also use different methods to compare your source code with another version of the file. You can search for a specific code, and even compare two different versions of the same document. This allows you to generate reports, which include the differences and the individual code, including line-by-line analysis. Pascal Analyzer can also automatically open files, which allows you to use an algorithm to generate missing or duplicated source code elements within your file. In addition, you can use the feature to compare a source code file with a reference version, or even a document in a specified version. You can use the Pascal Analyzer program to generate reports, which can be saved as XML files or CSV files. These reports can be viewed, saved and printed. The Pascal Analyzer application will help you detect code errors, issues with data types, syntax errors, unused code, warnings, code formatting, incorrect line lengths, or any other potential issue. The Pascal Analyzer program can be used with several different Delphi versions and with different compilers, including the newest XE6 for Android. It will even work with older Delphi versions, including Delphi 7, Delphi 6 and Delphi 5. The Pascal Analyzer program can be used to analyze and verify your project source code, program or property files. It can then help you identify any issues, such as code formatting, line count issues, unused code, redundant code or even compile time issues. It can then help you find potential issues with data types, and can generate reports with the different data types used within the project. It can also report on any code syntax or format issues that may occur, and

A macro replacement system for the PAS/A-Studio development environment. The KEYMACRO macro makes it possible to re-define common Pascal keywords in your Pascal source code. The macro is designed to replace token macros that typically require the use of a graphical macro editor. Instead, the macro can be replaced by typing a single keyword directly into the PAS/A-Studio editor. The macros are available for the following keywords: [ASIMPLE] Abbreviated name for *ASIMPLE* [CLASS] Indicates that a *CLASS* was encountered. [CONST] Indicates that a *CONST* was encountered. [CONST(A)] Indicates that a *CONST* with the optional default value of *A* was encountered. [DIM] Indicates that a *DIM* statement was encountered. [FOR] Indicates that a *FOR* statement was encountered. [IF] Indicates that an *IF* statement was encountered. [IFDEF] Indicates that an *IFDEF* directive was encountered. [IFNDEF] Indicates that an *IFNDEF* directive was encountered. [IMPORT] Indicates that an *IMPORT* statement was encountered. [IO] Indicates that an *IO* statement was encountered. [LOCAL] Indicates that a *LOCAL* statement was encountered. [MACRO] Indicates that a *MACRO* statement was encountered. [MESSAGE] Indicates that a *MESSAGE* statement was encountered. [NEW] Indicates that a *NEW* statement was encountered. [NOT] Indicates that a *NOT* statement was encountered. [OR] Indicates that an *OR* statement was encountered. [PROCEDURE] Indicates that a *PROCEDURE* statement was encountered. [REPEAT] Indicates that a *REPEAT* statement was encountered. [TO] Indicates that an *TO* statement was encountered. [TRY] Indicates that a *TRY* statement was encountered. [UNTIL] Indicates that an *UNTIL* statement was encountered. [WHILE] Indicates that a *WHILE* statement was encountered. [END] Ind 1d6a3396d6

Select which text to display in the code, as well as the language version. Main methods: Arguments: Any argument that is passed to the Main method. The Logic Block contains a set of statements or procedures that are executed in sequence. When you perform an operation such as an IF statement or a function call, the execution of the block is paused and the statements are evaluated from left to right. This statement or procedure is called a gate, and you can use gates in two different ways. When you use them with statements like IF and THEN, they act like a sequence of code that evaluates each statement in turn. For example, you can use the IF statement like so: IF true THEN DoSomething(); END IF You can also use gates to perform what is called a step-by-step operation, which executes a sequence of statements (the gate) as a single unit. For example, the following statement calls the procedure GetName, the sub-procedure PrintName, and then continues execution: PROCEDURE PrintName(name) Print(name); When you use a statement in this way, you can omit the THEN keyword and the ELSE keyword. To execute the statements in the order they appear in the procedure, you must use parentheses to create a sequence. For example, the following statement is a way to execute the IF and THEN statements in the order they appear in the procedure: PROCEDURE PrintName(name) Print(name); END PROCEDURE The SET statement is used to associate a variable name with a value. It is used like this: SET myName = "My name is Tom" PRINT myName The SET statement specifies the name of a variable, and the value it should be assigned to. The SET statement uses optional keywords, which you can specify to set a specific type of data. For example, the SET statement can be used to set a variable to a character or to a function. SET character Set a variable to a character. SET variable Set a variable to a function. The global statement is used to create a variable or procedure in the global scope, which is the space in the program where variables can be used without having to specify a specific scope. The SET statement has a long list of optional keywords. The most useful are: The debug statement is used to create a variable in the global scope
