A: It's a file format of fingerprints -- I thought it might be some sort of printer-dreck. The Wikipedia entry on it explains it, but for the n00b: Overview The term "Fingerprint Image" was proposed by the Federal Bureau of Investigation in their Fingerprint Identification System (FIS). It refers to the digital images of latent fingerprints taken as part of the FIS process, but is not restricted to such images. It may include palm prints, hand and foot prints, and various other types of casts or impressions of fingers, hands, feet, or objects. Fingerprint images are similar to photographs in many respects, with a few exceptions. One of the most significant is that the FBI states that fingerprint images are not "fingerprints", since the fingerprints are reproduced on film. Fingerprint images are often used for purposes other than identification, such as crime scene work and missing persons inquiries. A fingerprint image can be put into one of two states: a latent or a latent/copy. A latent fingerprint image is a picture of the fingerprint left in the environment where it was deposited. They can be left in a variety of environments, ranging from a fingerprint trap to a "dry" fingerprint on a paper bag. A latent fingerprint image also usually has a small number of overlaid "traces" which are small lines that contain incomplete information about the original fingerprint. A latent/copy fingerprint is an image of a fingerprint that has been magnified and electronically captured in such a way that a high degree of similarity to the original is achieved. This is almost invariably done by duplicating the image with the aid of some computer program. Until recently, latent/copy fingerprint images were most commonly viewed using optical scanners (typically flatbed scanners, although some slide scanners are also available). More recently, image magnifiers have become very popular, and some are capable of producing a printed image that is a close match to the original. Generally, a latent/copy fingerprint image is most useful in the same situations as a latent fingerprint. Efficacy and safety of liraglutide (

Both adaptive and innate immune systems play a central role in the pathogenesis of autoimmune diseases. Most of our knowledge on the biology of the human immune system has been obtained from studies of inbred laboratory mice, where the controlled generation of genetically defined strains is feasible. In contrast to the rather simple genetic architecture of inbred strains of mice, the genetic factors

controlling human autoimmune diseases appear to be far more complex and are influenced by a complex interplay between genetic and environmental factors, including the host's microbiome. The large
