It has been suggested that bone health is a potential determinant of long-term physical fitness and mortality and morbidity in adulthood. The aim of the present study was to examine the longitudinal relationships

between bone health in young adulthood and current lifestyle factors, body size and growth in adolescence, and to investigate the role of bone mass in explaining the variability of these relationships. This was a population-based cohort study, with data collected at 8 years of age (1993-1995) and 22 years of age (2001-2003). At 22 years of age, 91% of the subjects were recruited from the Oulu Health Survey, and the rest (9%) were participants of the Oulu Prospective Study of Pulmonary Hypertension
