The interaction of particles with different cell velocities gives rise to new dynamical phenomena, such as the formation of [*localized particle micro-clusters*]{}. We propose a simple phenomenological model of dynamic micro-clusters to describe the dynamics of the clustering of particles. The clustering dynamics consists in a set of equations for the evolution of particle number n, position r, and mean velocity u of the particles in the cell flow. The equations are non-local in space and time. We explore the asymptotic behavior of the equations, we study numerically the solution, and we check their accuracy by comparing with results from direct numerical simulations of the equations. Our analysis shows that the equations are accurate only as long as the components of the particle's velocity remain uncoupled.' address: - 'Institut de Physique du Globe de Paris, Ecole Normale Supérieure, 24 rue Lhomond, 75231 Paris Cédex 05, France' - 'Department of Mathematics, King Fahd University of Petroleum and Minerals, P.O. What's New In?

Assessment of different resistivity measurements in the investigation of contamination, surface and rock structure Resistivity is the impedance to the flow of electrical current in an electrical circuit. Diffusion is the movement of ions from one area to another. Concentration of ions in a solution is referred to as dilution. When sound travels through soil and rock, it is attenuated by a number of factors and this attenuation is proportional to frequency. The electrical conductivity of the various layers of rock and soil is widely used in research to determine the ratio of sound transmission through these layers. The thermal conductivity of soil and rock can be used to determine the temperature of hot material to which is applied, for example, the temperature of fire. Diffusivity is closely related to conductivity in that it is the rate of the conductivity of a material through a solid. When measuring electrical conductivity in a test hole, the most important factor to consider is overall stability of the mechanical conditions in the test hole. When making measurements in a hole, care must be taken to protect the instruments from the influence of mechanical disturbances. There are various methods to measure electrical resistivity in a test hole. Electrical resistivity measurements, commonly known as Resistivity Tomography, have been used in geology since the early 1970's and provide valuable information on the geology of subsurface rocks. Contact resistivity measurement (or contact resistivity measurement tomography (CRMT)) were introduced in the late 1970's. These systems are based on an attempt to decrease the effects of the bulk resistivity of the soil, and its consequent attenuation of the measured signals, by using the soil as an electrode. The method has been applied to investigations of buried geologic structures, and it has been suggested that the method has the potential to replace resistivity measurement systems which use a source electrode. Telefunken Urist resistivity (or neutron resistivity (NRMT)) was introduced in the 1980's. Like CRMT, it is based on an attempt to decrease the effects of the bulk resistivity of the soil, and its consequent attenuation of the measured signals. The method has been applied in geotechnical research and in further exploration of structures buried in rock and/or soil. Induced polarization resistivity (IPRT) was introduced in the late 1980's and is similar to Urist resistivity. The method also attempts to overcome the effects of bulk soil
