The recent sequencing of the entire genome of the human malaria parasite, Plasmodium falciparum, has made it possible to address questions about the organization and complexity of the var gene family. In order to determine the function of this var gene family, the restriction fragment length polymorphism (RFLP) pattern of individual var genes have been determined following digestion of a highly polymorphic region of the gene (block 2 of the var gene family). Using this data, as well as data from elsewhere in the genome, and the current assembly of the P. falciparum genome, the var locus has been divided into four chromosomal segments on the basis of their RFLP pattern. These chromosomes are 7.5, 6, 4, and 2.5 Mb in length. Five var genes are clustered on the 2.5 Mb chromosome and appear to have originated from a single var gene that originated on the 6 Mb chromosome. This same gene now appears to be reorganized on the 4 Mb chromosome. In contrast, a second var gene is located on the 7.5 Mb chromosome but has been inherited from the 6 Mb chromosome. Hence, the locus on the 4 Mb chromosome appears to be undergoing reorganization of the var gene family, suggesting that one of these var genes may have acquired a new role in the life cycle of the parasite., the best opportunity for phage therapy in the eyes of most patients, it is possible that certain populations of bacteria may be more or less prone to phage therapy.
