One approach being considered is nuclear magnetic resonance (NMR) quantum computing, a system based on a spin-coherent nuclear-spin system; see, for example, C. A. Weis et al. (1999), "Quantum-Computing Simulation of a Molecular Ising Model," Science 285, pp. 1293-1295 and R. Jozsa (1998), "Quantum Algorithms for the Ising Model," Review of Modern Physics 70, pp. 273-344. An NMR quantum computer consists of a group of spins in a glass tube, typically bonded to a bulk sample via a suitable molecule. The quantum state of each spin is represented by the direction of a small (i.e. microscopic) magnetic field. The spins are arranged so that they can be manipulated (i.e. flipped) by raising or lowering the temperature of the bulk magnetized sample above the spin's so-called transition temperature. A particular spin is flipped by applying a magnetic field pulse of appropriate duration and spatial direction. The field can be switched from positive to negative polarity, or vice versa. The NMR system comprises a number of separate components: the bulk sample (which may be human tissue); a field system for generating and switching magnetic fields at the appropriate points in the NMR system; a transmitter for applying the magnetic field pulses; and a receiver for detecting the magnetic-field pulses. In addition, the system includes an NMR probe for accessing selected volumes within the bulk sample, and a control system for controlling the temperature, the magnetic fields and the pulse sequence. The control system typically includes a computer (typically a Unix workstation) and various pieces of hardware, including a pulse programmer, a monitor and input/output (I/O) interfaces. The monitor provides a graphical interface to the user, who can control the NMR system via a mouse and keyboard, and can view a real-time video of the sample. The pulse programmer controls the pulse sequences. 648931e174
