Herpes simplex virus-thymidine kinase (HSV-TK) and cytosine deaminase (CD) gene therapy is an effective means of treating brain tumors. One of the more significant problems that limits the efficacy of CD/HSV-TK/cisplatin therapy is the toxicity of the drug to normal tissues. As a way of decreasing the toxicity and maximizing the efficacy of gene therapy, this study combines CD/HSV-TK into a single vector using the cytomegalovirus immediate early (CMV IE) promoter. This study focuses on the ability of the CMV-TK/CD gene to effectively transduce glioma cells and reduce the toxicity of the otherwise toxic drug. To determine if the CMV-TK/CD gene is efficiently incorporated into the glioma cells, an immunocytochemistry technique was used to detect both the transgene and the transfection marker beta-galactosidase. The results show that the CMV-TK/CD gene transduced tumor cells more effectively than the CMV-TK gene alone and the CMV-beta-galactosidase gene alone. The effectiveness of the CMV-TK/CD gene in reducing the toxicity of the CD/HSV-TK/cisplatin gene therapy was tested by comparing the viability of U118 glioma cells that were

transfected with the CD/HSV-TK/cisplatin gene to that of untransfected cells following cisplatin treatment. For more than 24 hours after cisplatin treatment, cell viability was reduced to a statistically significant level for U118 cells transfected with the CD/HSV-TK/cisplatin vector compared to cells transfected with the HSV-TK/
