Aldosterone hypersecretion is attributed to high intracellular cyclic AMP (cAMP) production in aldosterone-producing adenoma (Conn's syndrome). To elucidate the involvement of aldosterone and atrial natriuretic peptide (ANP) in the regulation of cAMP-producing mechanisms, we investigated the effects of these hormones on intracellular cAMP levels in adenomatous cells of aldosterone-producing adenoma (APA) in 12 cases. The results showed that the effect of aldosterone on cAMP production was not potent in the adenomatous cells

---

of APA compared to that in the normal tissue. The effect of ANP on cAMP production was similar in both normal and adenomatous cells. These findings indicate that aldosterone may not be considered to be responsible for the high cAMP production in APA.

Introduction ===== Successful limb salvage after the time of injury is a major objective of the surgeon in managing the patient with a scaphoid fracture. A bicolumnar repair is a surgical option that theoretically provides optimum results. It may be difficult to evaluate with current methods. One new surgical option is the use of radioisotopes to improve the success and outcome of healing of fractures. Results using this technique are promising and have yet to be evaluated to determine if they are still of benefit. Our aim was to evaluate the short term results of the treatment of scaphoid fractures with  $^{99m}\text{Tc}$  bone scan and the use of a special percutaneous scaphoid pinning in order to avoid the use of cast immobilization
